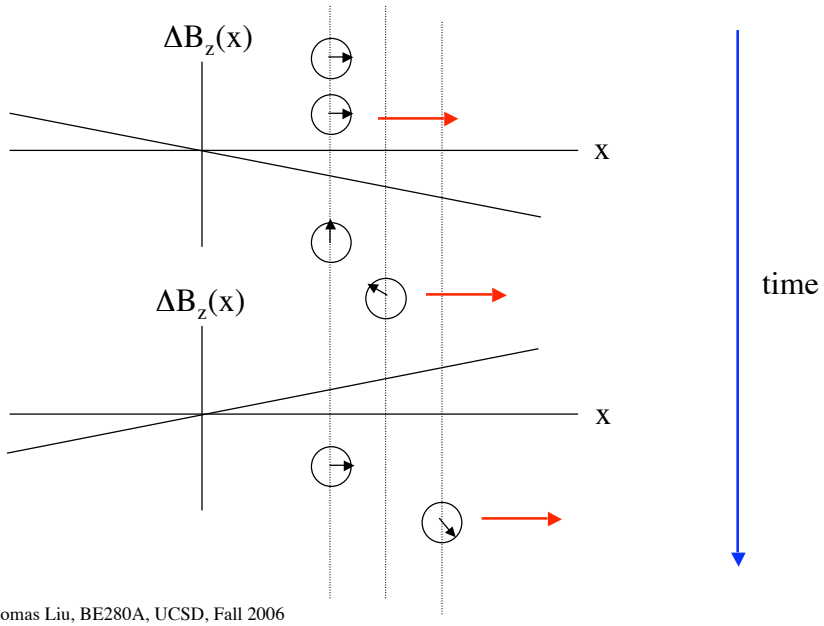
MRI Lecture 6

Moving Spins

So far we have assumed that the spins are not moving (aside from thermal motion giving rise to relaxation), and contrast has been based upon T_1, T_2, and proton density. We were able to achieve different contrasts by adjusting the appropriate pulse sequence parameters.

Biological samples are filled with moving spins, and we can also use MRI to image the movement. Examples: blood flow, diffusion of water in the white matter tracts. In addition, we can also sometimes induce motion into the object to image its mechanical properties, e.g. imaging of stress and strain with MR elastography.

Phase of Moving Spin



Phase of a Moving Spin

$$\begin{aligned}\varphi(t) &= -\int_0^t \Delta\omega(\tau)d\tau \\ &= -\int_0^t \gamma\Delta B(\tau)d\tau \\ &= -\int_0^t \gamma\vec{G}(\tau)\cdot\vec{r}(\tau)d\tau \\ &= -\gamma\int_0^t \left[G_x(\tau)x(\tau)+G_y(\tau)y(\tau)+G_z(\tau)z(\tau)\right]d\tau\end{aligned}$$

Phase of Moving Spin

Consider motion along the x-axis

$$x(t) = x_0 + vt + \frac{1}{2}at^2$$

$$\begin{aligned}\varphi(t) &= -\gamma \int_0^t G_x(\tau)x(\tau)d\tau \\ &= -\gamma \int_0^t G_x(\tau)\left[x_0 + v\tau + \frac{1}{2}a\tau^2\right]d\tau \\ &= -\gamma\left[x_0 \int_0^t G_x(\tau)d\tau + v\int_0^t G_x(\tau)\tau d\tau + \frac{a}{2}\int_0^t G_x(\tau)\tau^2 d\tau\right] \\ &= -\gamma\left[x_0 M_0 + vM_1 + \frac{a}{2}M_2\right]\end{aligned}$$

Phase of Moving Spin

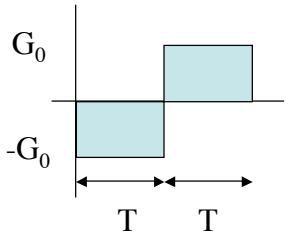
$$\varphi(t) = -\gamma\left[x_0 M_0 + vM_1 + \frac{a}{2}M_2\right]$$

$$M_0 = \int_0^t G_x(\tau)d\tau \qquad \text{Zeroth order moment}$$

$$M_1 = \int_0^t G_x(\tau)\tau d\tau \qquad \text{First order moment}$$

$$M_2 = \int_0^t G_x(\tau)\tau^2 d\tau \qquad \text{Second order moment}$$

Flow Moment Example



$$M_0 = \int_0^t G_x(\tau)d\tau = 0$$

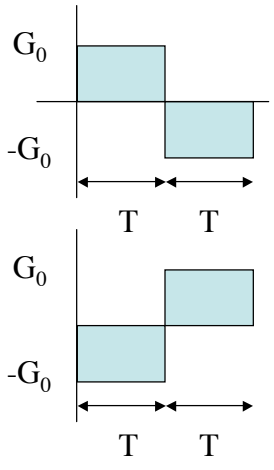
$$M_1 = \int_0^t G_x(\tau)\tau d\tau$$

$$= -\int_0^T G_0\tau d\tau + \int_T^{2T} G_0\tau d\tau$$

$$= G_0\left[-\frac{\tau^2}{2}\bigg|_0^T + \frac{\tau^2}{2}\bigg|_T^{2T}\right]$$

$$= G_0\left[-\frac{T^2}{2} + \frac{4T^2}{2} - \frac{T^2}{2}\right] = G_0T^2$$

Phase Contrast Angiography (PCA)



$$\varphi_1 = -\gamma v_x M_1 = \gamma v_x G_0 T^2$$

$$\varphi_2 = -\gamma v_x M_1 = -\gamma v_x G_0 T^2$$

$$\Delta\varphi = \varphi_1 - \varphi_2 = 2\gamma v_x G_0 T^2$$

$$v_x = \frac{\Delta\varphi}{2G_0T^2}$$

PCA example

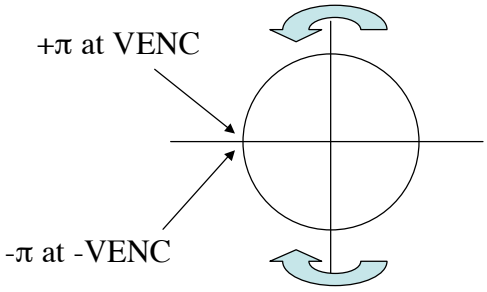
Aliasing in PCA

Define VENC as the velocity at at which the phase is 180 degrees.

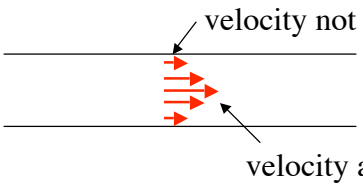
$$VENC \equiv \frac{\pi}{\gamma G_0 T^2}$$

Because of phase wrapping the velocity of spins flowing faster than VENC is ambiguous.



Thomas Liu, BE280A, UCSD, Fall 2006

Aliasing Solutions



Use data from regions with slower flow

Use multiple VENC values so that the phase differences are smaller than π radians.

$$\varphi_1 = \pi \frac{v_x}{VENC_1}$$

$$\varphi_2 = \pi \frac{v_x}{VENC_2}$$

$$\varphi_1 - \varphi_2 = \pi v_x \left(\frac{1}{VENC_1} - \frac{1}{VENC_2} \right)$$

Velocity k-space

A bipolar gradient introduces a phase modulation across velocities of the form $\varphi(v_x) = -\gamma v_x G_0 T^2$

We can make measurements with different amounts of phase modulation and then integrate over velocities to obtain

$$M(k_{v_x}) = \int_{-\infty}^{\infty} m(v_x) e^{j\varphi(v_x)} dv_x$$

$$= \int_{-\infty}^{\infty} m(v_x) e^{-j\gamma v_x G_0 T^2} dv_x$$

$$= \int_{-\infty}^{\infty} m(v_x) e^{-j2\pi k_{v_x} v_x} dv_x$$

$$= F\left[m(v_x)\right] \text{ with } k_{v_x} = \frac{\gamma}{2\pi} G_0 T^2$$

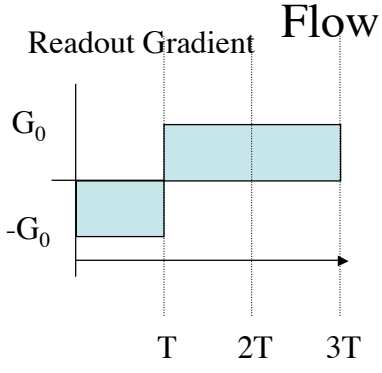
By making measurements with bipolar gradients of varying amplitudes/durations and taking the inverse transform of the measurements, we can obtain the velocity distribution.

Velocity k-space

$$M(k_x, k_{v_x}) = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} m(x, v_x) e^{-j2\pi k_x x} e^{-j2\pi k_{v_x} v_x} dx dv_x$$

In addition, we can apply imaging gradients so that we can eventually obtain the velocity distribution at each point in space. A full k-space acqusition would then yield 6 dimensions -- 3 spatial dimensions and 3 velocity dimensions.

Flow Artifacts

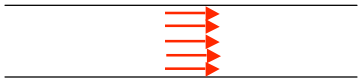


During readout moving spins within the object will accumulate phase that is in addition to the phase used for imaging. This leads to

1) Net phase at echo time TE = 2T.
2) An apparent shift in position of the object.
3) Blurring of the object due to a quadratic phase term.

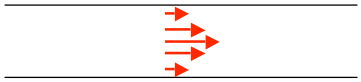
Flow Artifacts

Plug Flow



All moving spins in the voxel experience the same phase shift at echo time.

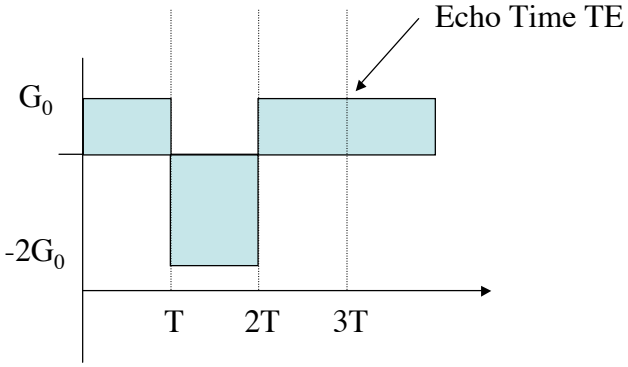
Laminar Flow



Spins have different phase shifts at echo time. The dephasing causes the cancelation and signal dropout.

Flow Compensation

Readout Gradient



At TE both the first and second order moments are zero, so both stationary and moving spins have zero net phase.

Inflow Effect

Cerebral Blood Flow (CBF)

CBF = Perfusion
= Rate of delivery of arterial blood to a capillary bed in tissue.

Units: $\frac{\text{(ml of Blood)}}{\text{(100 grams of tissue)(minute)}}$

Typical value is 60 ml/(100g-min) or 60 ml/(100 ml-min) = 0.01 s^{-1}, assuming average density of brain equals 1 gm/ml

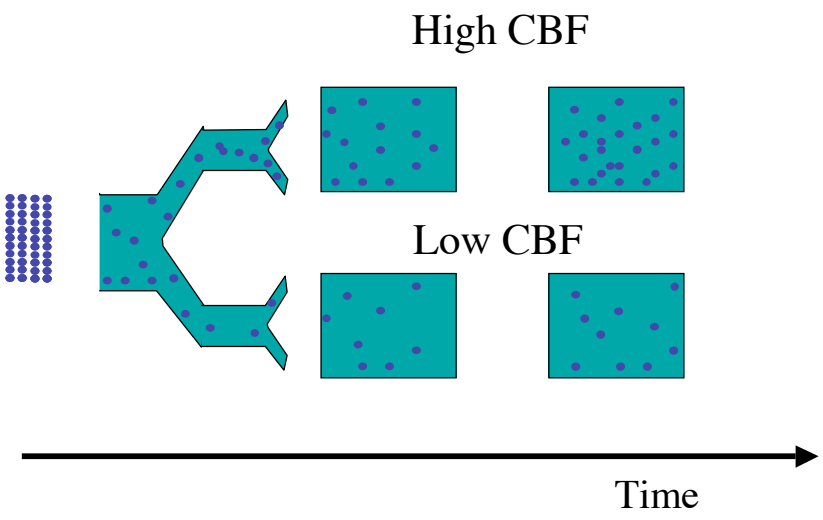
Buxton 2002



Arterial Spin Labeling

- Magnetically tag inflowing arterial blood
- Wait for tagged blood to flow into imaging slice
- Acquire image of tissue+tagged blood
- Apply control pulse that doesn't tag blood
- Acquire control image of tissue
- Control image-tag image = blood image

Thomas Liu, BE280A, UCSD, Fall 2006

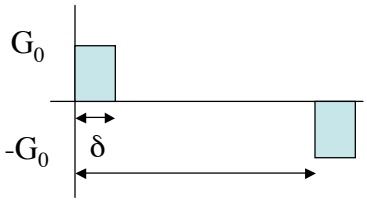
Diffusion Weighting



Assume $\delta << T$

$$\varphi(t_1) \approx -\gamma G_0 x(t_1)\delta$$

$$\varphi(t_2) \approx +\gamma G_0 x(t_2)\delta$$

Net Phase T

$$\varphi \approx \varphi(t_1) + \varphi(t_2) = \gamma G_0\left[x(t_2) - x(t_1)\right]\delta = \gamma G_0 \Delta x \delta$$

Average Squared Phase

$$\left\langle \varphi^2 \right\rangle = \gamma^2 G_0^2 \delta^2 \left\langle (\Delta x)^2 \right\rangle = \gamma^2 G_0^2 \delta^2 2DT$$

b-factor

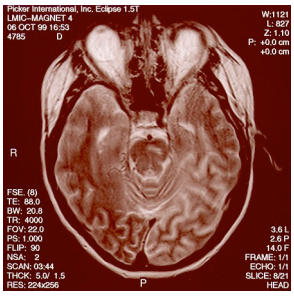
Signal

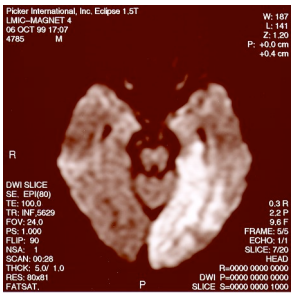
$$S \propto e^{-\left\langle \varphi^2 \right\rangle/2} = e^{-\gamma^2 G_0^2 \delta^2 DT} = e^{-bD} \quad \text{where } b = \gamma^2 G_0^2 \delta^2 T$$

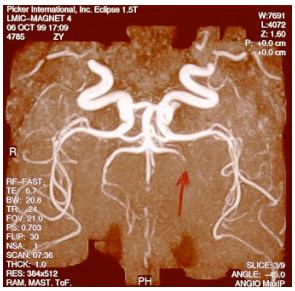
A more careful analysis yields $b = \gamma^2 G_0^2 \delta^2 (T - \delta/3)$

Diffusion Weighted Images

T2 weighted Diffusion Weighted Angiogram







After a stroke, normal water movement is restricted in the region of damage. Diffusivity decreases, so the signal intensity increases.

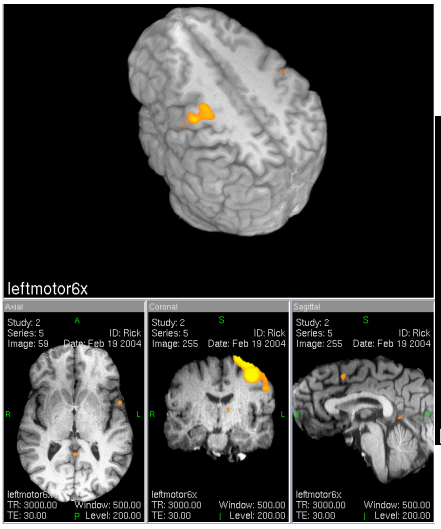
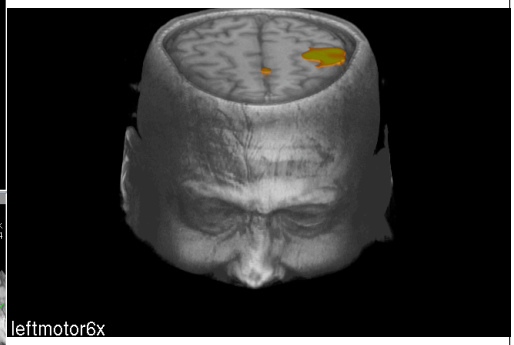
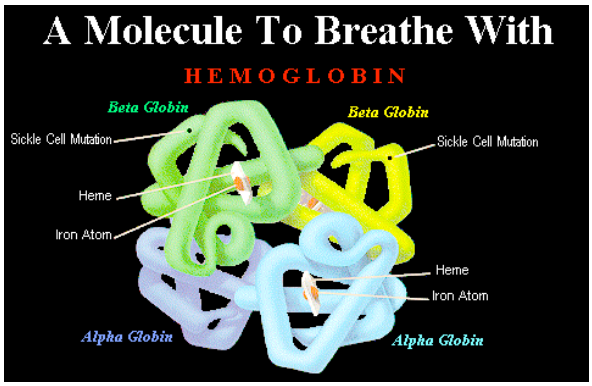
Finger Tapping Task





Hemoglobin



Oxygen binds to the iron atoms to form oxyhemoglobin HbO_2

Release of O_2 to tissue results in deoxyhemoglobin $dHBO_2$

http://www.people.virginia.edu/~rjh9u/hemoglob.html

Effect of $dHBO_2$

$dHBO_2$ is paramagnetic due to the iron atoms. As it becomes oxygenated, it becomes less paramagnetic.

$dHBO_2$ perturbs the local magnetic fields. As blood becomes more deoxygenated, the amount of perturbation increases and there is more dephasing of the spins. Thus as $dHBO_2$ increases we find that T_2^* decreases and the amplitude $\exp(-TE/T_2^*)$ image of a T_2^* weighted image will decrease. Conversely as $dHBO_2$ decreases, T_2^* increases and we expect the signal amplitude to go up.

Timeline

Michael Crichton, 1999

"Most people", Gordon said, "don't realize that the ordinary hospital MRI works by changing the quantum state of atoms in your body ... But the ordinary MRI does this with a very powerful magnetic field - say 1.5 tesla, about twenty-five thousand times as strong as the earth's magnetic field. We don't need that. We use Superconducting QUantum Interference Devices, or SQUIDs, that are so sensitive they can measure resonance just from the earth's magnetic field. We don't have any magnets in there".
